

## APPENDIX 7.6

### ROAD MODEL VERIFICATION

## APPENDIX 7.6 ROAD MODEL VERIFICATION

### Nitrogen Dioxide

Most nitrogen dioxide is produced in the atmosphere by the reaction of nitric oxide (NO) with ozone. It is therefore most appropriate to verify the model in terms of primary pollutant emission of nitrogen oxides ( $\text{NO}_x = \text{NO} + \text{NO}_2$ ). The model has been run to predict the 2015 annual mean road- $\text{NO}_x$  contribution at three monitoring locations (identified in Table 7.13). Concentrations have been modelled at a height of 1.5 m for Hillingdon Hays, 2.5 m for HD55 and 2 m for HD214.

The model output of road- $\text{NO}_x$  has been compared with the 'measured' road- $\text{NO}_x$ , which was calculated from the measured  $\text{NO}_2$  concentrations and the adjusted background  $\text{NO}_2$  concentrations within the  $\text{NO}_x$  from  $\text{NO}_2$  calculator.

A primary adjustment factor was determined as the slope of the best fit line between the 'measured' road contribution and the model derived road contribution, forced through zero (Figure 7.6.1). This factor was then applied to the modelled road- $\text{NO}_x$  concentration for each monitoring site to provide adjusted modelled road- $\text{NO}_x$  concentrations. The total nitrogen dioxide concentrations were then determined by combining the adjusted modelled road- $\text{NO}_x$  concentrations with the predicted background  $\text{NO}_2$  concentration within the  $\text{NO}_x$  from  $\text{NO}_2$  calculator. A secondary adjustment factor was finally calculated as the slope of the best fit line applied to the adjusted data and forced through zero (Figure 7.6.2).

The following primary and secondary adjustment factors have been applied to all modelled nitrogen dioxide data:

Primary adjustment factor: 1.4313

Secondary adjustment factor: 0.9989

The results imply that overall, the model was under-predicting the road- $\text{NO}_x$  contribution. This is a common experience with this and most other models.

Figure 7.6.3 compares final adjusted modelled total  $\text{NO}_2$  at each of the monitoring sites, to measured total  $\text{NO}_2$ , and shows the 1:1 relationship, as well as  $\pm 10\%$  and  $\pm 25\%$  of the 1:1 line.

**Figure 7.6.3: Comparison of Measured NO<sub>2</sub> with Fully Adjusted Modelled NO<sub>2</sub> Concentrations**

**Particle (PM<sub>10</sub> and PM<sub>2.5</sub>)**

The Hillingdon Hayes Automatic monitoring station has been used to calculate a verification factor for PM<sub>10</sub> following a similar methodology as that used for nitrogen dioxide.

Road PM<sub>10</sub> (calculated from Measured PM<sub>10</sub> at the Hillingdon Hays monitoring site and adjusted background PM<sub>10</sub> for the appropriate grid-square) is divided by the modelled road PM<sub>10</sub> to produce a factor which can be applied to PM<sub>10</sub> model outputs.

$$\text{Measured PM}_{10} (28 \mu\text{g}/\text{m}^3) - \text{Adjusted background PM}_{10} (19.8 \mu\text{g}/\text{m}^3) = \text{Measured Road PM}_{10} (8.2 \mu\text{g}/\text{m}^3)$$

$$\text{Measured Road PM}_{10} / \text{Modelled Road PM}_{10} (1.03 \mu\text{g}/\text{m}^3) = \text{PM}_{10} \text{ verification factor } (7.906).$$

No monitoring of PM<sub>2.5</sub> is carried out in proximity to the development site. The primary adjustment factor calculated for PM<sub>10</sub> concentrations has therefore been applied to the modelled road PM<sub>2.5</sub> particles concentrations.

2017

It should be noted that the measured road PM<sub>10</sub> is considerably higher than the modelled concentrations and therefore the high verification factor. The model may not take into account local factors that are likely to affect the measured concentration such as local industries with dust generating activities.
